Abstract: In this paper, a novel bacterial foraging algorithm (BFA) based approach for robust and optimal design of PID controller connected to power system stabilizer (PSS) is proposed for damping low frequency power oscillations of a single machine infinite bus bar (SMIB) power system. This paper attempts to optimize three parameters (K_p , K_i , K_d) of PID-PSS based on foraging behaviour of *Escherichia coli* bacteria in human intestine. The problem of robustly selecting the parameters of the power system stabilizer is converted to an optimization problem which is solved by bacterial foraging algorithm with a carefully selected objective function. The eigenvalue analysis and the simulation results obtained for internal and external disturbances for a wide range of operating conditions show the effectiveness and robustness of the proposed BFAPSS. Further, the time domain simulation results when compared with those obtained using conventional PSS and Particle Swarm Optimization (PSO) based PSS show the superiority of the proposed design.

1 Introduction

Power systems are highly non-linear and exhibit low frequency oscillations due to poor damping caused by the high-gain, fast-acting automatic voltage regulator (AVR) employed in the excitation system. The power system utilities employ power system stabilizers (PSSs) to introduce supplementary stabilizing signals into the excitation system to increase the damping of the low frequency oscillations. Among various types of PSSs, the fixed-structure lag-lead type is preferred by the utilities due to its operational simplicity and ease of tuning PSS parameters. However, the robustness of these PSS under changing conditions is a major concern.

The concept of PSSs and their tuning procedures were well explained in literature. A well-tuned lag-lead type PSS can effectively improve dynamic stability. Many approaches have been proposed to tune PSSs, such as the sensitivity approach [4], pole placement technique [2], and the damping torque approach [1]. Global optimization technique like genetic algorithm (GA) [5], Particle Swarm Optimization (PSO) [12], tabu search [6] and simulated annealing (SA) [7] are attracting the attention in the field of PSS parameter optimization in recent times. But when the system has a highly epistatic objective function (i.e., where the parameters being optimized are highly correlated) and number of parameters to be optimized are large, GA has been reported to exhibit degraded efficiency [8]. Bacterial foraging algorithm has been proposed and introduced as a new evolutionary technique in [9]. Passino et al. pointed out that the foraging algorithms can be integrated in the framework of evolutionary algorithms. To overcome the drawbacks of conventional methods for PSS design, a new optimization scheme known as bacterial foraging (BF) is used for the PSS parameter design. This algorithm (BFA) appeared as a promising one for handling the optimization problems [13]. It is a computational intelligence based technique that is not largely affected by the size and nonlinearity of the problem and can converge to the optimal solution in many cases where many analytical methods fail to converge. Considering the strength of this algorithm, it is employed in the present work for the optimal tuning the parameters of the PSS.

In this paper a new/improved BFA-based optimal determination of PID-PSS parameters is presented which overcomes the shortcomings of previous works. In order to design a robust PSS which guarantees stability of system in a wide range of operating conditions, the objective function is defined such that the resultant time response is restricted to lie within specific bounds as well as limiting the amount of overshooting of power system response when subjected to disturbances. The performance of the BFAPSS is compared with those obtained with other techniques such as conventional and Particle Swarm Optimization (PSO) by plotting the time response curves for step disturbance. Further, the robustness of the controller so designed is established by choosing any one set of parameters for a particular operating condition and testing its performance with its fixed structure for other operating conditions too.

2 Power System Model Studied

The system considered in this paper is a synchronous machine connected to an infinite bus through a transmission line, as shown in Figure 1. The linear incremental model of a synchronous machine connected to a large system is shown in Figure 2.

The state equation under a particular loading condition can be written as [1].

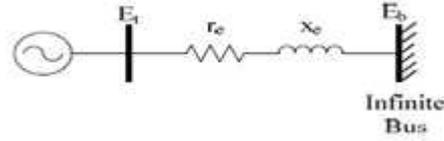

Figure 1: Single Machine connected to Infinite Bus System.

$$dx(t)/dt = Ax(t) + Bu(t), \quad (1)$$

$$y(t) = Cx(t), \quad (2)$$

where $x(t)$ is the state vector, $u(t)$ is the control input and $y(t)$ is the output and A, B, C are the matrices of appropriate dimensions. The following physical variables are chosen as the state and output for the power system under consideration.

$$x(t) = [\Delta(t) \quad \Delta\omega(t) \quad \Delta E q'(t) \quad \Delta E f d(t)]^T, \quad (3)$$

$$y(t) = [0 \quad 1 \quad 0 \quad 0]. \quad (4)$$

The system matrices as taken from [1] are given below

$$A = \begin{bmatrix} 0 & 314 & 0 & 0 \\ -K1/M & -D/M & 0 & 0 \\ -K4/M & 0 & -1/K3T'do & 0 \\ KeK5/Ta & 0 & -K6Ke/Te & -1/Te \end{bmatrix},$$

$$B = [0 \quad 0 \quad 0 \quad Ke/Te], \quad (5)$$

$$C = [0 \quad 1 \quad 0 \quad 0]. \quad (6)$$

The parameters K1-K6 in system matrix A are functions of real power output P and reactive power output Q of the generator [11, 12]. Thus it is observed that the elements of the A matrix change as the operating point of the generator changes. When the system is perturbed it is possible that it becomes unstable or operates with sustained oscillations. It is therefore necessary to design a PSS which will guarantee stability of the system and suppress these unwanted oscillations. Further, it is necessary to change the PSS parameters according to the drift in the operating conditions.

The main objective of this work is to design the power system stabilizer using Bacterial Foraging Algorithm such that the controller structure so designed rejects the internal and external disturbances and is immune to machine parameters variations.

3 Particle Swarm Optimization

Particle Swarm Optimization (PSO) is a population based stochastic optimization technique developed by Eberhart and Kennedy [12]. It shares many similarities with evolutionary computation techniques such as Genetic Algorithms (GA). The system is initialized with a population of random particles where each particle is a candidate solution.

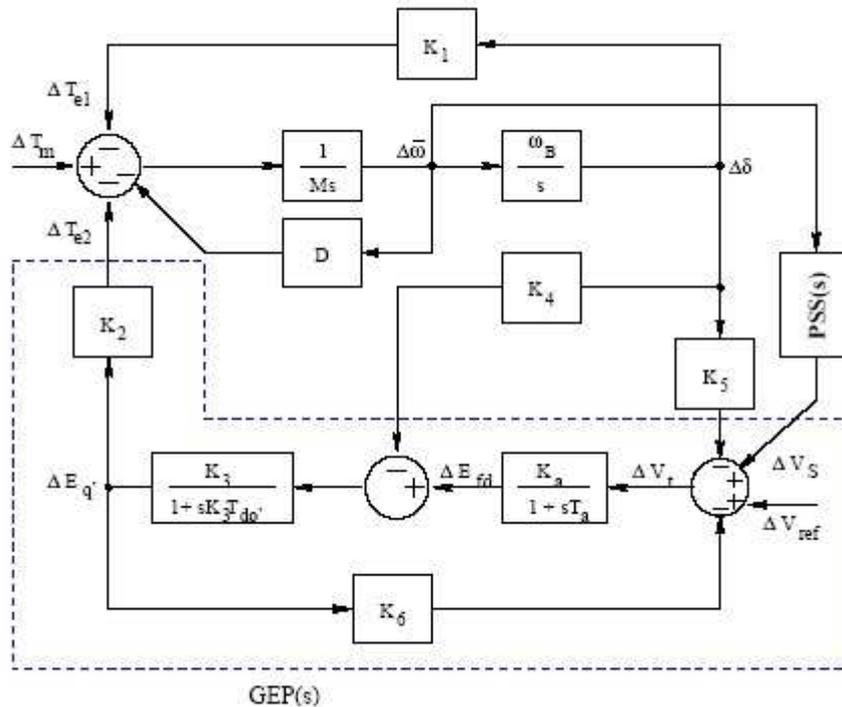

Figure 2: Linearized model of a synchronous machine with an exciter and stabilizer.

The particles fly through the problem space by following the current optimum particles and searches for optima by updating their positions. However, unlike GA, PSO has no evolution operators such as crossover and mutation. The advantages of PSO over GA are the ease of programming and fast convergence [8, 9]. In the PSO algorithm, each particle updates its velocity and position by the following relationships:

$$V_i^{k+1} = wV_i^k + c1rand1(pbest_i - S_i^k) + c2rand2(gbest_i - S_i^k), \quad (7)$$

$$S_i^{k+1} = S_i^k + V_i^{k+1}, \quad (8)$$

where $c1$ and $c2$ are cognition and social parameters respectively, $rand1()$ and $rand2()$ are constant numbers in the range of $[0,1]$, w is the inertia weight. V_i represents the velocity of the i^{th} particle and S_i is its position, $pbest_i$ and $gbest_i$ are local best and global best positions respectively. The velocity of particle in equation (7) depends on its previous velocity, its own thinking and social psychological adaptation of the population. The PSO algorithm starts with random initialization of population and velocity. The search for the optimum solution is continued unless one of the stopping criteria is reached. The stopping criteria are: either the maximum iterations are reached, or there is no further improvement in the optimal solution. The values of parameters for PSO used in this study are as follows: No. of particles 20; No. of swarms 3 (Kp, Ki, Kd); No. iteration=

500; Maximum particle velocity (upper-lower bound) / No. iteration = 0.05; $c_1, c_2 = 2, 2$; $w_{max} = 0.9, w_{min} = 0.4$.

To compute the optimum parameter values of PID-PSS shown in Figure 4, a 0.1 step change in reference mechanical torque (ΔTm) is assumed and the performance index in equation (9) is minimized using Particle Swarm Optimization. The settling time (ts) and peak overshoot ($\Delta\omega p$) are evaluated for each iteration.

4 Bacterial Foraging Algorithm

Bacterial foraging algorithm is inspired by an activity called "chemotaxis" exhibited by bacterial foraging behaviors. Motile bacteria such as E. coli and salmonella propel themselves by rotation of the flagella. To move forward, the flagella rotates counterclockwise and the organism "swims" or "runs" while a clockwise rotation of the flagellum causes the bacterium to randomly "tumble" itself in a new direction and swim again. Alternation between "swim" and "tumble" enables the bacterium to search for nutrients in random directions. Swimming is more frequent as the bacterium approaches a nutrient gradient. Tumbling, hence direction changes, is more frequent as the bacterium moves away from some food to search for more. Basically, bacterial chemotaxis is a complex combination of swimming and tumbling that keeps bacteria in places of higher concentrations of nutrients. The foraging strategy of Escherichia coli bacteria present in human intestine can be explained by three processes, namely chemotaxis, reproduction, and elimination-dispersal [9].

In Chemotaxis, a unit walk with random direction represents a "tumble" and a unit walk with the same direction in the last step indicates a "run". $C(i)$ is called the run length unit parameter, is the chemo tactic step size during each run or tumble. With the activity of run or tumble at each step of the chemotaxis process, a step fitness will be evaluated. In the reproduction step, all bacteria are stored in reverse order according to the health status. Here only the first half of the population survives, and a surviving bacterium splits into two identical ones, which are then placed in the same locations. Thus, the population of bacteria keeps constant. It is possible that in the local environment, the life of a population of bacteria changes either gradually by consumption of nutrients or suddenly due to some other influence. Events can kill or disperse all the bacteria in a region. They have the effect of possibly destroying the chemotactic progress, but in contrast, they also assist it, since dispersal may place bacteria near good food sources. Elimination and dispersal helps in reducing the behavior of stagnation (i.e., being trapped in a premature solution point or local optima). The flow chart of the iterative algorithm is shown in Figure 3.

The bacteria with large run length unit $C(i)$ have the exploring ability and stay for a while in several domains containing local optima. It can also escape from the local optima to enter the domain with global optima. On the other hand, a bacterium with small run length unit $C(i)$ is attracted into the domain with local optima and exploits this local minimum for its whole life cycle. It is therefore necessary to choose the value of $C(i)$ with larger value for faster convergence. In this algorithm, cost function value is taken as objective function and the bacterium having minimum cost function (J) is retained for the next generation. For swarming, the distances of all the bacteria in a new chemotactic stage are evaluated from the global optimum bacterium till that point. To speed up the convergence, a simple heuristic rule to update one of the coefficients (C) of BFA algorithm is formulated.

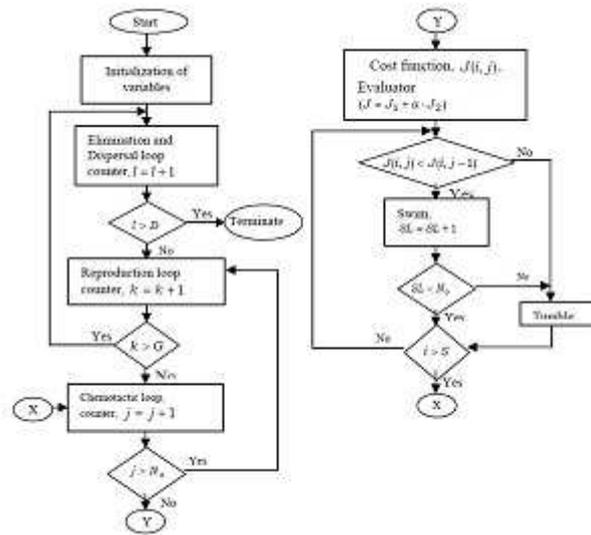

Figure 3: Flowchart of Bacterial Foraging Algorithm.

5 BFA based Tuning of PID-PSS

PID (proportional integral derivative) control is one of the earlier control strategies. Its early implementation was in pneumatic devices, followed by vacuum and solid state analog electronics, before arriving at today’s digital implementation of microprocessors. It has a simple control structure which was understood by plant operators and which they found relatively easy to tune. Since many control systems using PID control have proved satisfactory, it still has a wide range of applications in industrial control. It has been found possible to set satisfactory controller parameters from less plant information than a complete mathematical model. In the proposed design approach, the PID control structure shown in Figure 4 is used as the power system stabilizer as opposed to the traditional lead-lag controller. In Figure 4, the speed deviation is the input to the

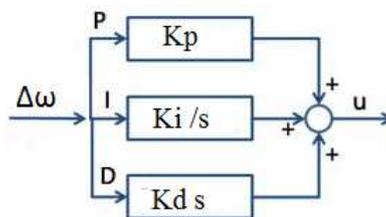

Figure 4: The PID power system stabilizer.

controller and u is the supplementary stabilizing signal. The PID parameters $K_p, K_i,$

and Kd are tuned using the BFA technique discussed in Section 4. To compute the optimum parameter values, a 0.1 step change in reference mechanical torque (ΔTm) is assumed and the performance index

$$F = \frac{1}{(1 + \Delta\omega p)(1 + ts)} \quad (9)$$

is minimized using bacterial foraging algorithm. The settling time (ts) and peak overshoot ($\Delta\omega p$) are evaluated for each iteration. The PID parameters selected using the above objective function are used to form the augmented A matrix as given below:

$$\begin{pmatrix} 0 & 314 & 0 & 0 & 0 \\ -K1/M & 0 & -K2/M & 0 & 0 \\ -K4/T'd0 & 0 & -1/K3T'do & 1/T'do & 0 \\ MKe(-K5 + MKi/314 - KdK1)MTe & KeKp/Te & -MK6Ke - K2KeKd/Te & 1/Te & Ke/Te \\ MKi/314 - KdK1/MTw & Kp/Tw & -K2Kd/MTw & 0 & -1/Tw \end{pmatrix}.$$

The following machine parameters are chosen for study $xd = 1.6; x'd = 0.32; xq = 1.55; vt0 = 1.05; \omega = 100rad/s; T'd0 = 6.0s; D = 0.0; M = 10.0; re = 0; xe = 0.4; Ke = 50.0; Te = 0.05s; T = 5s$. The parameters for BFA used in this study are as follows: $Nc = 5, Nre = 4, Ned = 10, Ns = 4, datt = 0.01, hrep = 0.01, watt = 0.4, wrep = 0.42, w = 0.8, c1 = 2.0$ and $c2 = 2.0$.

6 Tuning Results and Discussion

Simulation tests were made using a computational program that represents the single machine connected to infinite bus bar system. The machine with PID-PSS is represented as 5th order state space model with saturation neglected.

The different operating conditions [2] considered are given in Table 1. The simulation study for the operating conditions mentioned using Bacterial Foraging Algorithm (BFA) is carried out for a step disturbance of 0.1 mechanical torque (ΔTm). Simulation study is also carried out for the mentioned operating conditions for the PSS designed using conventional and Particle Swarm Optimization (PSO). The conventional PSS parameters are calculated using frequency response method. The PSS parameters obtained by the application of conventional, PSO and BFA along with the corresponding eigenvalues are shown in Table 2. From Table 2, it is observed that the real parts of closed loop eigenvalues obtained using BFAPSS are shifted to the left half of the s -plane which provides more damping. The time response specifications obtained from the transient response curves are shown in Table 3.

From Figures 5–7 and Table 3, it is observed that the performance of the PSS designed using BFA is far superior compared to the PSS designed using conventional as well as Particle Swarm Optimization (PSO). Figure 8 illustrates the convergence of the objective function with Particle Swarm Optimization (PSO) and BFA. From the convergence characteristics it is clear that BFA offers superior performance than (PSO). Figure 9 shows the speed deviation for different operating conditions with BFA PSS when the system is subjected to 0.1 p.u step disturbance in the reference input voltage ($\Delta Vref$).

In power system the operating condition changes very fast. The controller designed for one operating condition may not give satisfactory performance to other operating conditions. Therefore, it becomes necessary that the controller parameters need to be tuned according to the changes in the operating condition which is very difficult to

accomplish online even using very fast computer. Therefore it is necessary to design a PSS which is robust in behaviour. From Table 2 the eigen values obtained for the power system with BFAPSS do not change appreciably which suggests the robustness of the PSS. It is therefore possible to choose the PSS parameters obtained by BFA at any one operating condition which can be chosen and retained for other operating conditions also.

7 Conclusion

In this study, optimal design of robust power system stabilizer (PSS) for single machine system using Bacterial Foraging Algorithm is proposed. Eigenvalue analysis under different operating conditions reveals that undamped and lightly damped oscillation modes are shifted to a specific stable zone in the s -plane. These results show the potential of Bacterial Foraging Algorithm for optimal design of PSS parameters. Further, from the

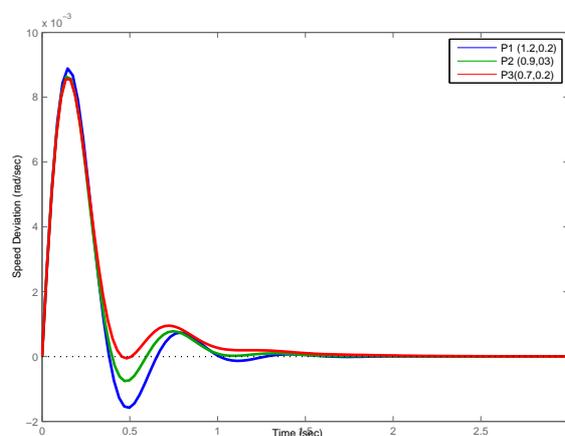

Figure 11: Speed deviation for different operating conditions using PSOPSS with $K_p = 40.997$, $K_i = 7.6503$, $K_d = 6.30605$.

simulation results it is observed that, when a system is subjected to internal and external disturbances by retaining the same structure and parameter of the controller which was obtained for any one operating condition works effectively over a wide range of loading conditions which is very difficult to accomplish on line. This shows the robustness of the controller designed using BFA. Furthermore, the simulation results also show that the proposed method in this paper gives much improved performance when compared to the performance of conventional and Particle Swarm Optimization (PSO) based design of controller for PSS. Further, the convergence of the objective function in the proposed method is much faster when compared with Particle Swarm Optimization (PSO).

In this paper, the linear incremental model of single machine connected to infinite bus has been considered for the design of PID controller even though the actual system is highly non-linear one and therefore it becomes necessary to validate the results obtained here by laboratory test which has been taken for future work. The Bacterial Foraging Algorithm (BFA) remains to be tried out for designing controllers in the capacitive area and also for multi-machine complex power system.
