**Abstract:** Description of all possible types of behavior, or evolution, of solutions to a semilinear sectorial equation is given. The phase space is divided into separate regions containing bounded solutions, grow-up solutions and those which blow up in a finite time. An overview of results concerning the typical situation when solutions of various types of behavior coexist is given and illustrated by chosen examples of reaction-diffusion equations.

**Keywords:** *parabolic equation; sectorial equation; Cauchy problem; global solutions; grow-up solutions; blow-up solutions; comprehensive description.*

**Mathematics Subject Classification (2010):** Primary 35B40; Secondary 35B60, 35K15, 70K05, 93D30.

## 1 Introduction

This paper is devoted to the fundamental question connected with solutions of semilinear sectorial equations (1) being generalizations of parabolic equations: *Provided that a local in time solution exists, what is the expected future for the rest of its existence?*

It is known from the classical references, such as [20, Chapter I], that, in general, there are three potential forms of the further evolution of such solutions:

- the local solution may *blow up*, which means that its phase space norm becomes unbounded in a finite time; in general, it can be a consequence of unboundedness of the values of the solution or the values of some of its derivatives, even though the solution itself may stay bounded in the  $L^\infty$ -norm,
- the local solution may *grow up*, that is, it will exist for all positive times, while some of its norms will become unbounded as  $t \rightarrow \infty$ ,
